Robótica - Entregable 2

Versión básica

El robot inicia los módulos « torres » en el cual se elige el punto de origen de la torre y el numero de piezas a desplaza. A partir de ahí, desplaza todas las piezas hacia un lado de la torre inicial para crear una torre intermedia y finalmente vuelve a desplazar todas las piezas al otro lado del punto de inicio para volver a poner las piezas en el orden inicial. Cuando termina de desplazar todas las piezas vuelve a su posición de reposo.

Versión avanzada(I)

El robot inicia los módulos "torres", en primer lugar el robot desactiva su ventosa y vuelve a la posición de reposo. Se calcula las posiciones de las torres gracias a la circunferencia y al numero de torres definidos. A partir de ahí empieza a desplazar las piezas gracias a un bucle sobre las piezas y las desplaza hacia sus posiciones de destino. He utilizado el resultado de la división euclidiana de la iteración en la que nos encontramos por el numero de torres ya que su resultado nos da la altura a la que debe dejar la pieza el robot y su resto permite saber a que torre hay que llevar la pieza.
